

CS459/698

Privacy, Cryptography, Network and Data Security

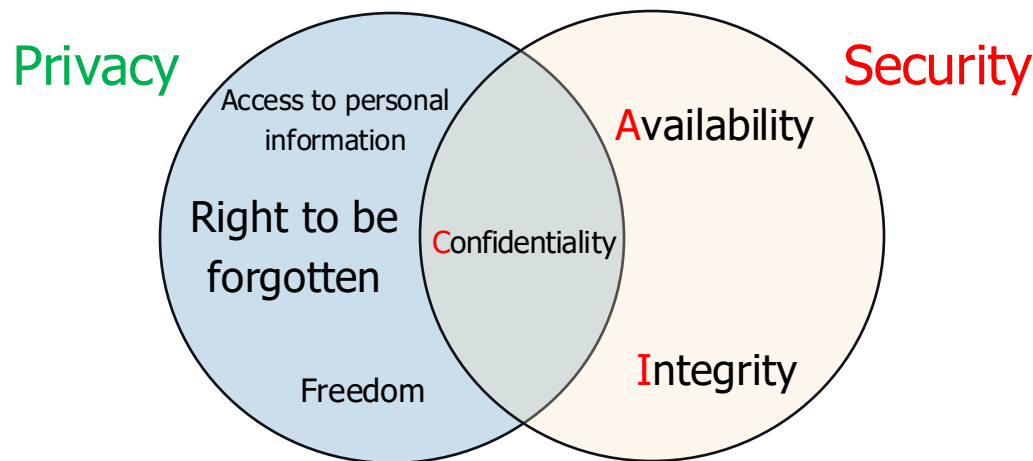

Basics of Cryptography

Fall 2024, Tuesday/Thursday 02:30pm-03:50pm

Quick recap

- Security and Privacy? (rights vs responsibilities)

- Explored how can we distinguish between privacy & security
- Defined, **what** is being protected, from **who**, and under what **conditions** this protection will hold.
- Gave a loose definition of assets, vulnerabilities, threats and attacks.

This lecture

- Identify attack techniques and apply them (Cryptanalysis)
 - Cryptanalysis: studies cryptographic systems to look for weaknesses or information leakage
- Explain building blocks of cryptography
 - Cryptography: Show how to send secure messages over an insecure medium (eg. Internet)
- Explain how modern cryptography properties arose

Goal: Why does Basically, know what cryptography tools exist and how to securely use them. Build a foundation of primitives for more complicated “applied cryptography” later.

Steganography- Secretly “hidden” messages

The same image viewed by white, blue, green, and red lights reveals different hidden numbers.

Cryptography – Cast of characters

(Honest) communicating parties

Alice

Bob

Carol

Dave

Adversaries

Eve

Mallory

- Eve: a passive eavesdropper who can **listen** to transmitted messages
- Mallory: an active Man-In-The-Middle, who can **listen** to, **and modify, insert, or delete**, transmitted messages.

Components of Cryptography

- **C**onfidentiality

- Preventing Eve from **reading** Alice's messages

- **I**ntegrity

- Preventing Mallory from **Modifying** Alice's messages without being detected

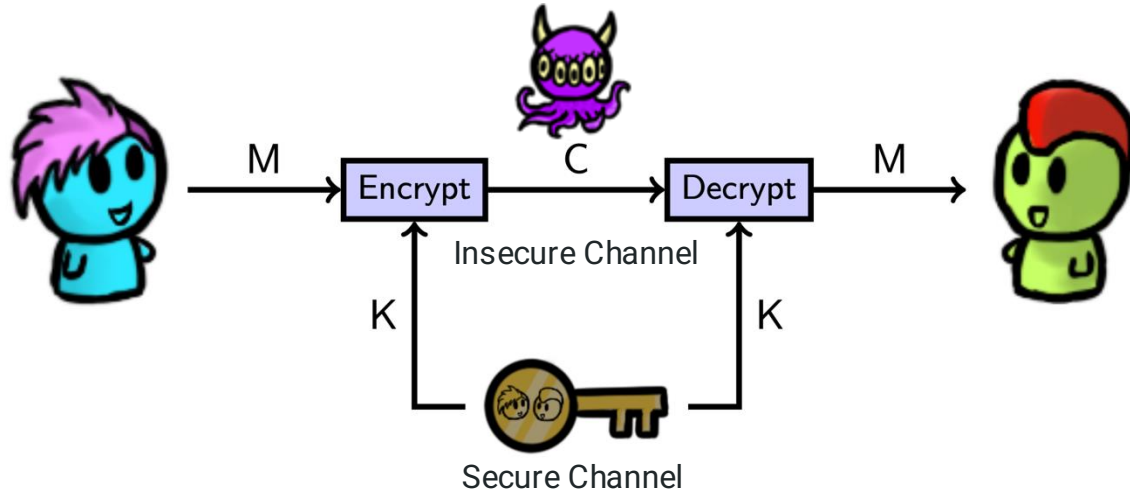

- **A**uthenticity,

- Preventing Mallory from **impersonating** Alice

Cryptography - Path for Secret Messages

- Secret-key encryption (**symmetric encryption**) is the simplest form of cryptography.
- The key Alice uses to encrypt the message is the same as the key Bob uses to decrypt it
- Eve, not knowing the key, should not be able to recover the plaintext

CRYPTOGRAPHY

Substitution Cipher (shift 3):

Caesar Cipher

Image source: wikipedia

Caesar Cipher

Substitution Cipher (shift 13)

Image source: wikipedia

Shift and Substitution Ciphers

Replace symbols (letters) by others

- Using a rule e.g., $y = x + 13 \pmod{26}$, Caesar's cipher Key: 13
- Using a keyword e.g, Key: table(t=a shift of 20.)

Cryptanalysis - Analyzing “secret” messages

Mwahaha

We will learn the
secretsssss.

GRAP

Shannon's maxim!!!! (design
assuming adversaries will
learn the algorithm)

VHRTPYEYTISAOI

Transposition Cipher

Kerckhoff's Principle

- **Kerckhoff's principle:** a cryptosystem should be secure, even if everything about the system, except the **key**, is public knowledge.
 - The system is at most as secure as the number of keys(shortcuts to finding the key)

Kerckhoff's Principle

- **Shannon's maxim:** we should design systems under the assumption that the enemy will immediately gain full familiarity with them.
 - Don't use "secret" encryption methods (security by obscurity)
 - Have **public** algorithms that use a **secret key** as input (easier to change the key than the whole system)

Vernam Cipher

- **Encrypts one bit at a time by XOR'ing the plaintext with the key:**

- Plaintext (t bits): $M = [m_1, m_2, \dots, m_t]$
- Key (t bits): $K = [k_1, k_2, \dots, k_t]$
- Ciphertext (t bits): $C = [c_1, c_2, \dots, c_t] = [m_1, m_2, \dots, m_t] \oplus [k_1, k_2, \dots, k_t]$
- XOR reminder:

$$0 \oplus 0 = 0$$

$$0 \oplus 1 = 1$$

$$1 \oplus 0 = 1$$

$$1 \oplus 1 = 0$$

Q: How do we decrypt ?

A: $[m_1, m_2, \dots, m_t] = [c_1, c_2, \dots, c_t] \oplus [k_1, k_2, \dots, k_t]$

- If K is randomly chosen and never reused, Vernam cipher is called **One-Time Pad**

One-time Pad

- Vernam cipher: $C = M \oplus K$
- If K is randomly chosen and never reused, Vernam cipher is called **One-Time Pad**
 - This provides **Information-Theoretic security** (The key must be truly random \neq PRG).

Q: Why does “trying every key” not work here ?

A: Because, given a ciphertext C , for every possible message M , there exist a key K that could have generated that ciphertext.

Well, this sucks for me...

Two-time Pad?

Q: What happens if we use the same key K (therefor, same keystream) ?

Ciphertext₁ = Message₁ \oplus K = 2c1549100043130b1000290a1b

Ciphertext₂ = Message₂ \oplus K = 3f16421617175203114c020b1c

Hmmm... how can I relate these messages together?

Two-time Pad?

A: We can XOR the ciphertexts: $C_1 \oplus C_2 = (M_1 \oplus K) \oplus (M_1 \oplus K) = M_1 \oplus M_2$

Ciphertext₁ \oplus Ciphertext₂ =

Message₁ \oplus K \oplus Message₂ \oplus K =

Message₁ \oplus Message₂ = 13030b0617544108014c2b0107

Two-time Pad?

Message₁ \oplus Message₂ = 13030b0617544108014c2b0107

Suppose Message₁ starts with “Alice” (416C696365)

- Message₂ seems to start with readable text (“Rober”)

Is “Alice” here...?

Two-time Pad?

Message₁ \oplus Message₂ = 13030b0617544108014c2b0107

Suppose It starts with “Alice and Bob” (416C69636520616E6420426F62)

- Message₂ is fully readable now (“Rober feline”)

Ahaaa!

Two-time Pad?

Messages are not purely random!

- A “two-time pad” is **insecure!**
- The key must **never be used more than once**
- The key must be as long as the message

C_1

C_2

$C_1 \oplus C_2$

M_2

M_1

So...Cryptography?

- Simple substitution/transposition is insecure
- One-Time Pad is inefficient over the secure channel
 - Keys as long as messages – think about encrypting GBs of data!

Goal: Securely communicate “a lot” of information on an insecure channel while requiring “limited” communication over a secure channel

Now what?

Substitution is **insecure**...

Transposition is **insecure**...

Key reuse using XOR (one-time pad) is **insecure**...

BUT...

Repeat it often enough and it can be regarded as **secure**

Now what?

Substitution is **insecure**...

Transposition is **insecure**...

Key reuse

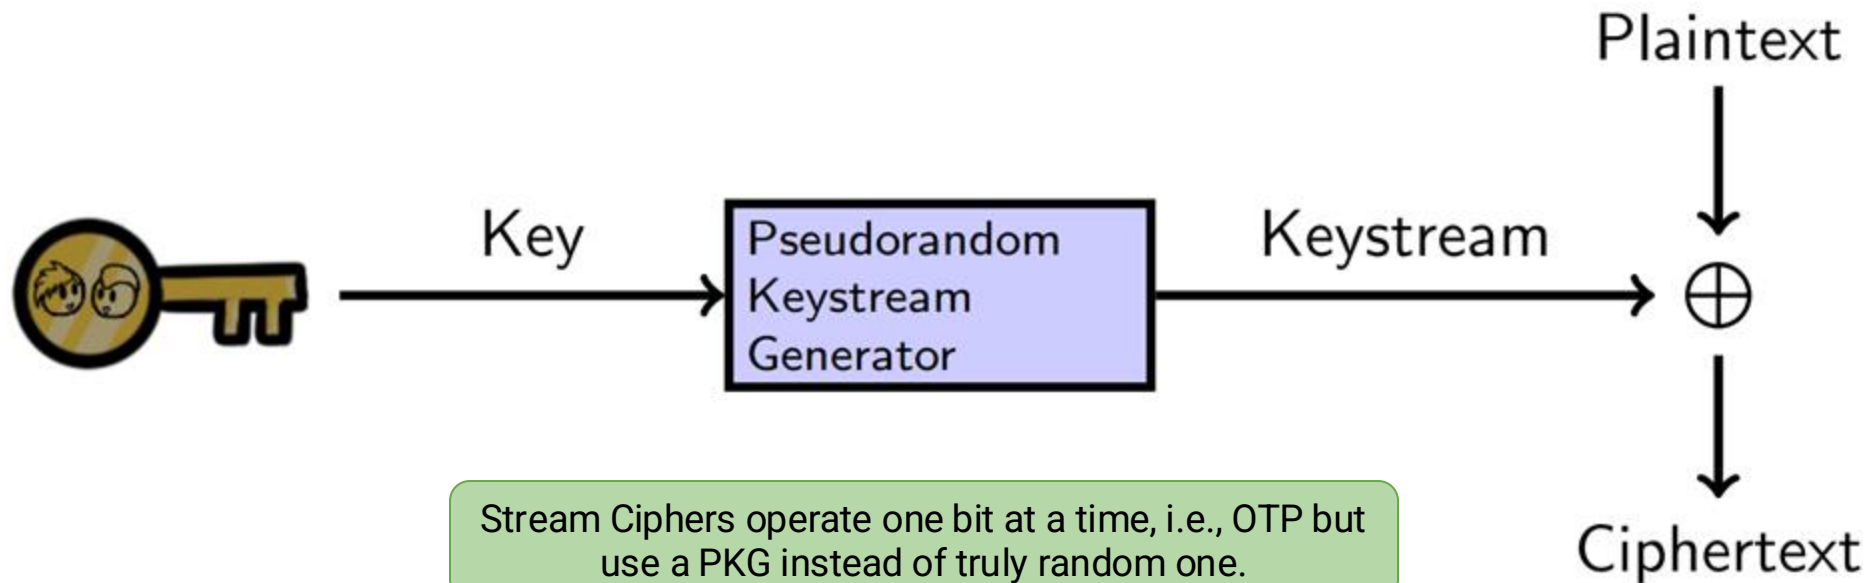

Stream Ciphers and Block
Ciphers

... is **insecure**...

BUT...

Repeat it often enough and it can be regarded as **secure**

Stream Cipher?

Fun(?) Facts:

- RC4 was the most common stream cipher on the Internet but deprecated.
- ChaCha increasingly popular (Chrome and Android), and SNOW3G in mobile phone networks.

Stream Ciphers Share Conditions with OTP

- Stream ciphers can be **very fast**
 - This is useful if you need to send a lot of data securely
- But they can be **tricky** to use correctly!
 - We saw the issues of re-using a key! (**two-time pad**)
 - **Solution:** concatenate key with nonce (which does not need to be a secret)

Fun(?) Facts:

- WEP, PPTP are great examples of how **not** to use stream ciphers. "Susceptible to dictionary attacks and brute-force attacks"

Bit by bit.... but do you have to?

- Weakness of streams...one bit at a time?
 - What happens in a stream cipher if you change just one bit of the plaintext?

Bit by bit.... but do you have to?

- Weakness of streams...one bit at a time?
 - What happens in a stream cipher if you change just one bit of the plaintext?

A: You only change a bit in the ciphertext

Bit by bit.... but do you have to?

- Weakness of streams...one bit at a time?
 - What happens in a stream cipher if you change just one bit of the plaintext?

A: You only change a bit in the ciphertext

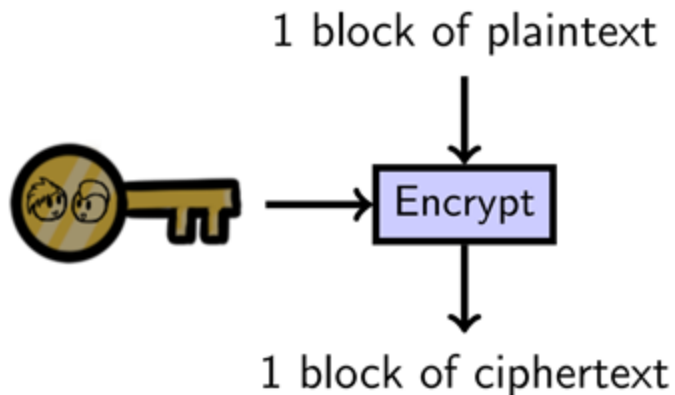

Q: Can we do better?

Bit by bit.... but do you have to?

- Weakness of streams...one bit at a time?
 - What happens in a stream cipher if you change just one bit of the plaintext?

A: You only change a bit in the ciphertext

Q: Can we do better?

Block Ciphers !!!

Block Ciphers

- Welcome, use of block ciphers
 - Block ciphers operate on the message **one block** at a time
 - Blocks are usually 64 or 128 bits long
- **AES**, the current standard
 - You better have a very...**very good reason** to choose otherwise

Two Catches with Block Ciphers

- Message is **shorter** than one block?
 - Requires padding
- Message is **longer** than a block?
 - Requires **modes of operation** <new concept>

Electronic Code Book (ECB) mode

- Encrypts each successive block separately

⋮ ⋮ ⋮

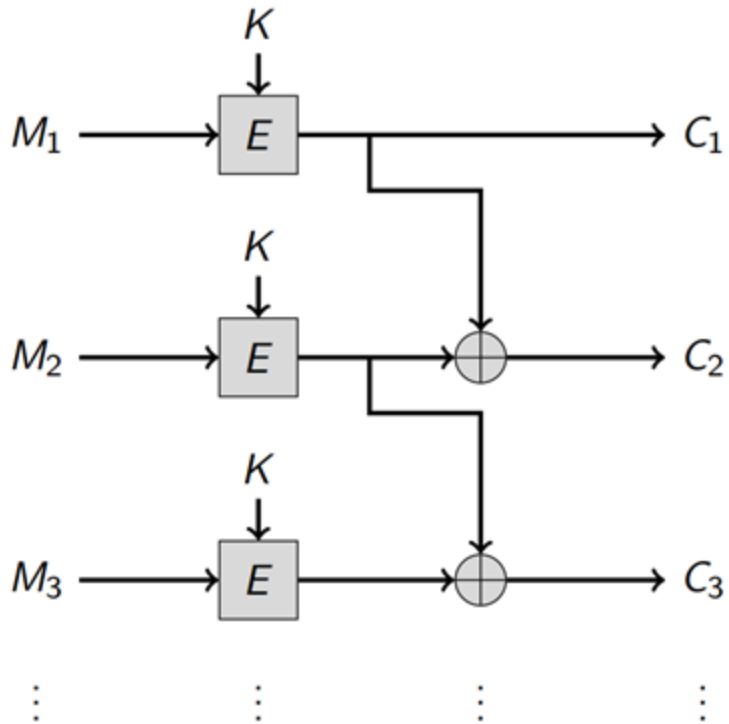

Q: What happens if the plaintext M has some blocks that are identical, $M_i = M_j$?

A: $C_i = E_K(M_i), C_j = E_K(M_j) \Rightarrow C_i = C_j$

This reveals the pattern in the ciphertext...

Improving ECB (V_1)

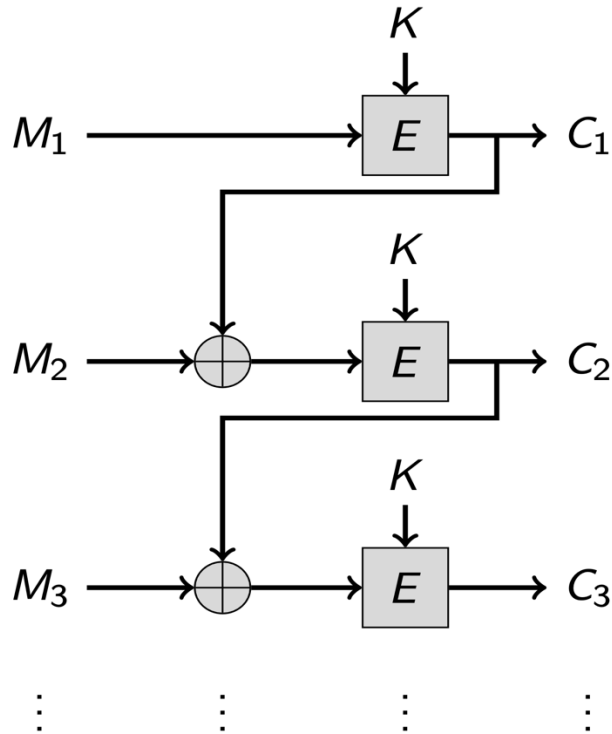

- We can provide “**feedback**” among different blocks, to avoid repeating patterns

Q: Does this avoid repeating patterns? Are there other issues?

A: We can un-do the XOR if we get all the ciphertexts. This basically does not improve compared to ECB.

Improving ECB (V₂)

Q: Spot the difference?

Q: Does this avoid repeating patterns among blocks?

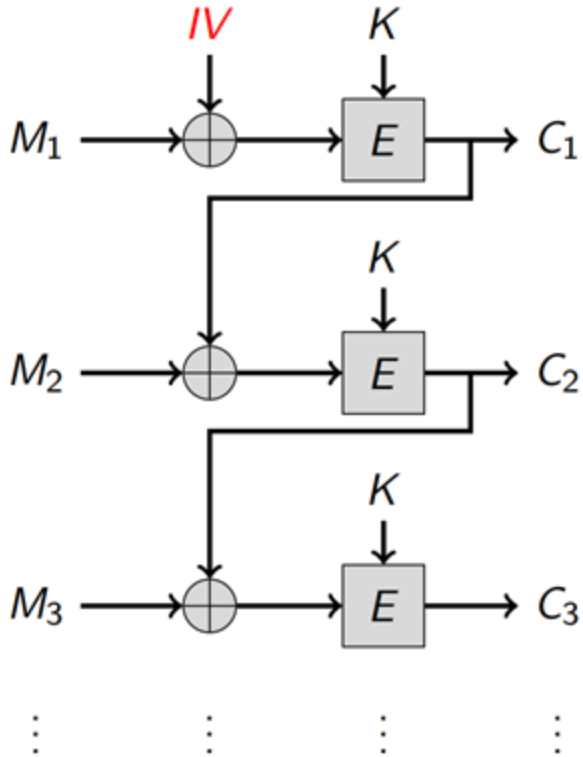

Q: What would happen if we encrypt the message twice with the same key?

A: $C_1 = E_K(M)$, $C_2 = E_K(M) \Rightarrow C_1 = C_2$

We could change the key... but there is a better way

Cipher Block Chaining (CBC) mode

Q: Does this solve the issue of encrypting equal blocks?
Does this solve the issue of encrypting equal messages/plaintexts?

A: Yes! **CBC mode**

Q: Can we share IV in the clear?

A: Yes!!!

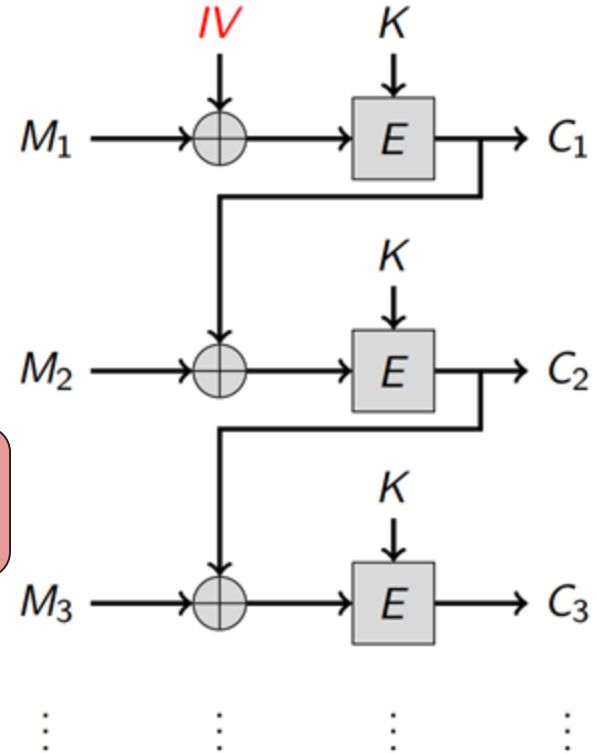

An **Initialization Vector** might also be called as a **nonce** (number used once) or **salt**.

CBC Recap:

1. Generate a secret key K
2. Encrypt M using K and a generated IV
3. Decrypt C using K and the IV to get M

Security Goal: Indistinguishability under adaptive chosen ciphertext attack (IND-CCA2)

Cipher Security, IND-CCA2

Indistinguishability under Adaptive Chosen Ciphertext Attack

Adaptive chosen
ciphertext attack

Eve exploits the ability to interact with the decryption oracle.

Cipher Security, IND-CCA2

Indistinguishability under Adaptive Chosen Ciphertext Attack

Adaptive chosen
ciphertext attack

ACCA: **Eve** exploits the ability to interact with the decryption oracle.

IND-CCA: Even if **Eve** can choose ciphertexts to be decrypted and has access to the decrypted results, they cannot distinguish between two different plaintexts based on their ciphertexts

Cipher Security, IND-CCA2

Indistinguishability under Adaptive Chosen Ciphertext Attack

Adaptive chosen
ciphertext attack

A bunch of
useless
ciphertexts!!!

Eve cannot distinguish whether
 C_i is from M_1 , M_2 or M_3

Common modes of operation

- There are different modes of operation
 - e.g., Cipher Block Chaining (**CBC**), Counter (**CTR**), and Galois Counter (**GCM**) modes
- Patterns in the plaintext are no longer exposed because these modes involve some kind of “**feedback**” among blocks.
 - But you need an **IV**

So...now what?

- How do Alice and Bob share the secret key?
 - Meet in person; diplomatic courier...
- In general this is very hard

Or, we invent new technology!!

Spoiler Alert: it's already been invented...

Stay tuned!

Until next time...
