CS459/698 Privacy, Cryptography, Network and Data Security

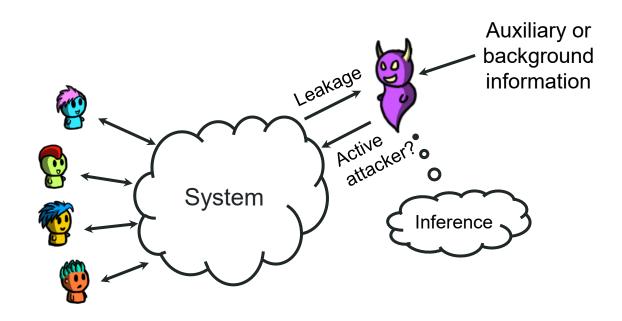

Inference Attacks

A2 is due today!

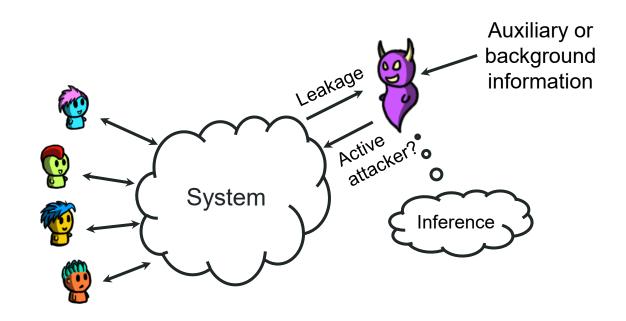

- Late policy from today 3pm until Nov 8 3pm.
 - No further help will be provided

What are inference attacks?

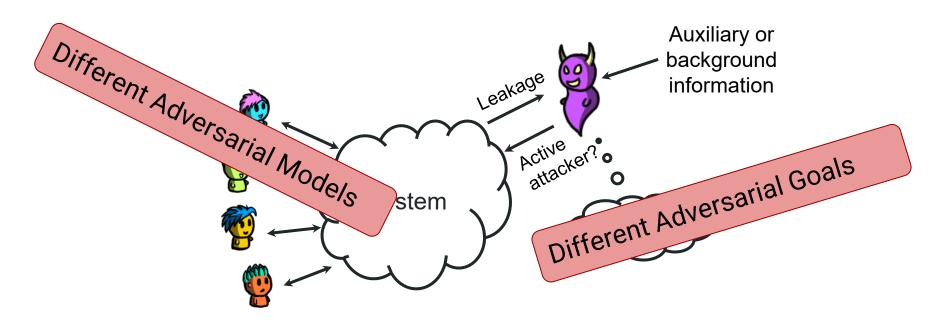

What are inference attacks?

Goal: Learn something (non-trivial) and privacy sensitive from the system

What are inference attacks?

Goal: Learn something (non-trivial) and privacy sensitive from the system

Context for Inference Attacks: The Model

- Attacks generally rely on information "leakage"
- The leakage can be intentional:
 - Sending usage statistics to a service provider (Microsoft, Apple, ...)
 - Reporting our location to Google Maps
 - Publishing census data
- Some leakage is unintentional:
 - E.g., side-channels: you saw these earlier!

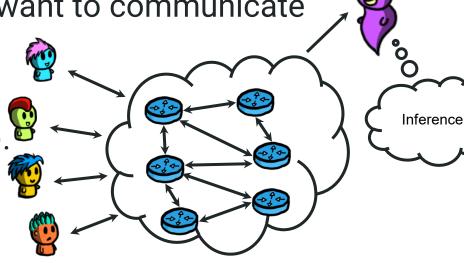

Attacks can combine all leaked information with auxiliary information to infer non-trivial sensitive data!

• **Adversary:** A passive adversary observing all flows of traffic in a network.

Functionality: The users want to communicate with each other

(they don't intend to leak

anything to an adversary)

Auxiliary or

background information

- Adversary: A passive adversary observing flows of traffic in a network.
- Functionality: The users want to communicate with each other
 (they don't intend to leak anything to an adversary).

Leakage:

- Packet payload
- Packet headers
- Timing information

Inference

- Adversary: A passive adversary observing flows of traffic in a network.
- Functionality: The users want to communicate with each other
 (they don't intend to leak anything to an adversary).

Inference

Leakage:

Packet payload

Packet headers

Timing information

Q: What non-trivial privacy-sensitive information could the adversary infer?

- Adver flows
- Func

with

(they

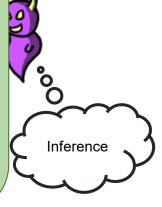

anyth

Δ:

- What the users are talking about
- Who is talking with whom
- The social graph of the users

- Whether or not a particular data sample was in the training set
- A general property of the training population
- Given partial data about a user, learn other attributes about the user

• ...

Leakage:

- Inferences from the ML model

Q: What non-trivial privacy-sensitive information could the adversary infer?

Why study inference attacks?

Adversarial Thinking

 Think like an adversary to understand the vulnerabilities of a system and develop protection techniques.

 With inference attacks, we also apply Kerckhoffs's principle (or Shannon's maxim), adapted to privacy

Adversarial Thinking

 Think like an adversary to understand the vulnerabilities of a system and develop protection techniques.

 With inference attacks, we also apply Kerckhoffs's principle (or Shannon's maxim), adapted to privacy

Assume the adversary knows how the system works

- there are no hidden parameters other than the users' data
- the adversary can even know some rough distribution that the users' data follows

Designing a System Aware of Inference Attacks

For any system that relies on users' data, there are two goals:

- **Utility:** Design a system that provides benefits to its users and the service provider
- Privacy: Design a system that provides protection against inference attacks

Q: What are "utility" and "privacy"? How do we "measure" them?

Designing a System Aware of Inference Attacks

For any system that relies on users' data, there are two goals:

- **Utility:** Design a system that provides benefits to its users and the service provider
- Privacy: Design a system that provides protection against inference attacks

Recall, what is privacy?

Usable Privacy

What is Privacy?

- Useful definition: **informational self-determination**"The right of the individual to decide what information about himself should be communicated to others and under what circumstances" (Westin, 1970)
- Privacy is having control over:
 - Who we share our data with
 - Who they can share it with
 - For what purpose they use it
 - o Etc.

Quantifying Privacy

- Protecting the sensitive information, e.g., not just data, also meta-data, relationships, timing, whether a user participated in a system, etc.
- Quantifying privacy is very hard

There is **no cure-all metric** for privacy. Measuring privacy can be computationally intractable, etc.

Quantifying Privacy: Theoretical Notions

- Syntactic notions of privacy: these are computed on the leaked or released data. They are data dependent
 - K-anonymity, l-diversity, t-closeness, etc

Quantifying Privacy: Theoretical Notions

- **Syntactic** notions of privacy: these are computed on the leaked or released data. They are data dependent
 - K-anonymity, l-diversity, t-closeness, etc
- Semantic notions of privacy: these are computed on the data release mechanism itself, and they hold regardless of the data (data independent)
 - Differential Privacy

Quantifying Privacy: Empirical Notions

- The performance of an **inference attack**, e.g., the attacker error, accuracy, true positive rate, false positive rate, etc
- Can provide an **upper bound** on privacy

Quantifying Privacy: Empirical Notions

- The performance of an inference attack e.g., the attacker error, accuracy, true positive rate, false positive rate, etc
- Can provide an upper bound on privacy

Q: Why an upper bound?

Quantifying Privacy: Empirical Notions

- The performance of an inference attack e.g., the attacker error, accuracy, true positive rate, false positive rate, etc
- Can provide an upper bound on privacy

Q: Why an upper bound?

A: Can't get more privacy if this attack succeeds

Utility and Privacy

Utility

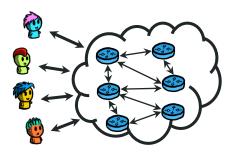

Definition: the benefit that users (and the provider) get from using the system.

Utility

Definition: the benefit that users (and the provider) get from using the system.

Communications system:

For users: being able to communicate

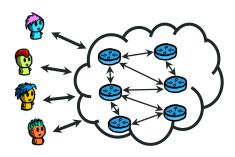

Utility

Definition: the benefit that users (and the provider) get from using the system.

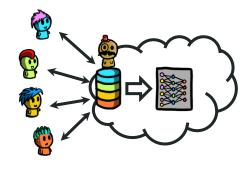

Communications system:

For users: being able to communicate

Machine learning:

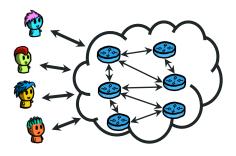

- For participants: maybe they get compensation?
- For data owner: it can sell access to the model for revenue
- Analysts: they pay to get benefits from the model's outputs
- General public: maybe the model outputs are good for society?

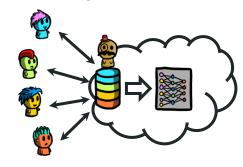

Quantifying Utility

Q: How do we *quantify* utility?

Communications system:

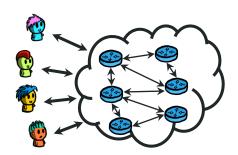

Machine learning:

Quantifying Utility

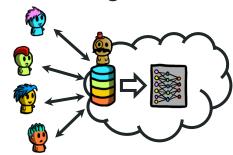

Q: How do we *quantify* utility?

Communications system:

- Few packets dropped
- High bandwidth/throughput
- Low latency/delay...

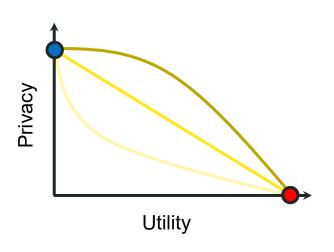

Machine learning:

- Useful model (high test accuracy)
- Unbiased model (low disparity among subpopulations)
- Low computational requirements to build the model
- Fast training algorithm...

The Privacy-Utility Trade-off

 Given any metric for privacy and for utility, they are usually at odds:

- Q: How do you design a system that provides maximum utility?
- Q: How do you design a system that provides maximum privacy?
- Designing a system that provides a good privacy-utility trade-off is hard!

The Privacy-Utility trade-off

 Given any metric for privacy and for utility, they are usually at odds:

- How do you design a system that provides maximum utility?
 - You design it without privacy in mind
- How do you design a system that provides maximum privacy?
 - You don't design it
- Designing a system that provides a good privacy-utility trade-off is hard!

Inference Attacks: Goals and Techniques

- As we saw before, the attacker can have different goals:
 - Infer data
 - Infer a property of the data
 - Infer the presence (membership) of some data
 - Infer the behavior of a user
 - Infer some attributes of a data sample
 - Infer dependencies among the data
 - O ..

Inference Attacks: Goals and Techniques

- As we saw before, the attacker can have different goals:
 - Infer data
 - Infer a property of the data
 - Infer the presence (membership) of some data
 - Infer the behavior of a user
 - Infer some attributes of a data sample
 - Infer dependencies among the data
 - o ..

- There are different techniques to perform an inference attack:
 - Statistics (estimation theory, maximum likelihood, Bayesian inference...)
 - Combinatorics
 - Heuristics
 - Machine learning
 - O ...

Inference Attack Examples

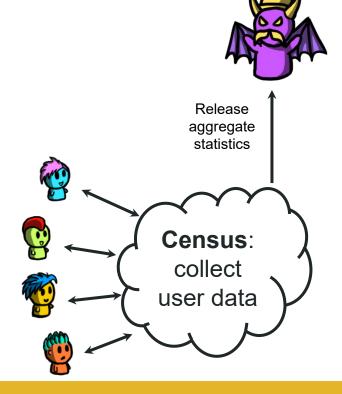

Inference attacks: examples

- For the rest of the lecture, we will see examples of inference attacks with different goals and techniques.
- You need to understand these attacks, their goal, the leakage they exploit and the techniques they use.
 - Given a new system, with some leakage specification and an attack goal, you should be able to come up with reasonable privacy/utility metrics and an inference attack.

We will see:

- 1. Census reconstruction attacks
- 2. SQL inference attacks (tracker attacks)
- 3. Database reconstruction attacks
- 4. Statistical inference attacks
 - Maximum Likelihood
 - Maximum A-Posteriori
- 5. ML inference attacks
- 6. Linking attacks

- A census involves collecting lots of privacy-sensitive data.
- Some useful aggregate statistics are released.
- The adversary tries to infer (reconstruct) some individuals' data.

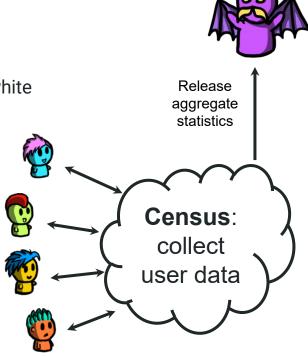

- A census involves collecting lots of privacy-sensitive data.
- Some useful aggregate statistics are released.
- The adversary tries to infer (reconstruct) some individuals' data.
- Example:

Background data: adversary knows a participant that self-identifies as white is 35 years old and participants self-identifying as asian have same age.

Released aggregates:

	COUNT	AGE MEAN
Total population	4	24
White	2	26
Asian	2	22

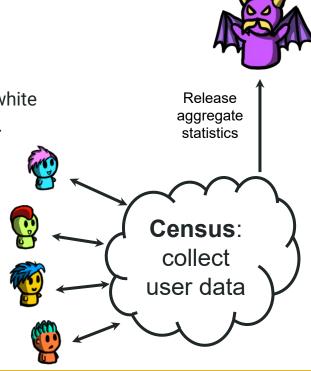

- A census involves collecting lots of privacy-sensitive data.
- Some useful aggregate statistics are released.
- The adversary tries to infer (reconstruct) some individuals' data.
- Example:

Background data: adversary knows a participant that self-identifies as white is 35 years old and participants self-identifying as asian have same age.

Released aggregates:

	COUNT	AGE MEAN
Total population	4	24
White	2	26
Asian	2	22

Q: Can you guess the age and self-identified race of every participant?

- A census involves collecting lots of privacy-sensitive data.
- Some useful aggregate statistics are released.
- The adversary tries to infer (reconstruct) some individuals' data.
- Example:

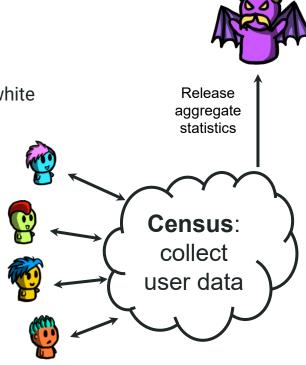

Background data: adversary knows a participant that self-identifies as white is 35 years old and participants self-identifying as asian have same age.

Released aggregates:

	COUNT	AGE MEAN
Total population	4	24
White	2	26
Asian	2	22

Q: Can you guess the age and self-identified race of every participant?

Hypothesis: W1=35, W2=17, A1=22, A2=22

Another example, no background information:

Q: Can you guess the self-identified race, age, and marital status?

	COUNT	AGE MEAN	AGE MEDIAN
Total population	4	40	37.5
White	2	50	50
Asian	2	30	30
Single	1	25	25
Married	3	45	40

Another example, no background information:

Q: Can you guess the self-identified race, age, and marital status?

	COUNT	AGE MEAN	AGE MEDIAN
Total population	4	40	37.5
White	2	50	50
Asian	2	30	30
Single	1	25	25
Married	3	45	40

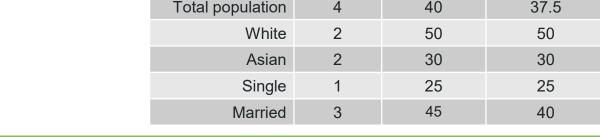

A: If you assume the single person is Asian, A1=25, then A2=35.

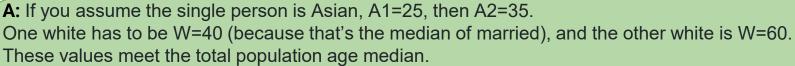

One white has to be W=40 (because that's the median of married), and the other white is W=60. These values meet the total population age median.

Another example, no background information:

Q: Can you guess the self-identified race, age, and marital status?

	COUNT	AGE MEAN	AGE MEDIAN
Total population	4	40	37.5
White	2	50	50
Asian	2	30	30
Single	1	25	25
Married	3	45	40

If you do the same assuming the single is White, you get W1=25, W2=75, A1=40, A2=20, which does not meet the age median result, so it can't be true.

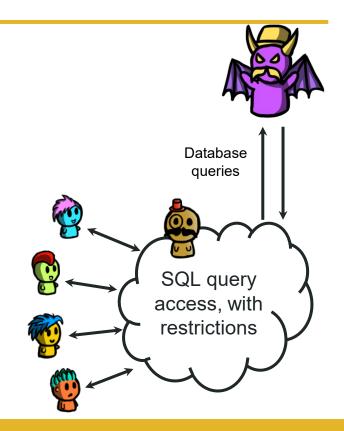

2. SQL Query Attacks

2. SQL query attacks

- A data collector creates a relational database (table) with data from different clients.
- An adversary can issue SQL queries to gather data from the table.
- The database management system allows queries with the following syntax:

SELECT SUM(ATTRIBUTE) FROM (TABLE) WHERE (CONDITION)

 However, any queries that match fewer than X entries or more than N-X entries are discarded.

2. SQL query attacks: example

- The table Employees has four attributes:
 - Names are unique
 - Ages are between 18 and 65
 - Position is either 'full time' or 'part time'
 - Salaries are between 50k and 500k

Name	Age	Position	Salary
Alice	40	full time	120k
Carol			

- You know Carol is in the dataset, and that around 50% of the people are 'full time'.
- There are N records in the dataset; any query that matches fewer than $\frac{N}{10}$ or more than $\frac{9N}{10}$ entries is discarded.
- Can you recover Carol's salary? How many queries do you need?

SELECT SUM(ATTRIBUTE) FROM (TABLE) WHERE (CONDITION)

2. SQL query attacks: solution

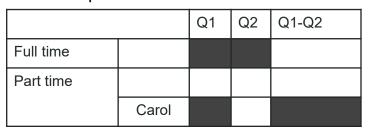

• There are N records in the dataset; any query that matches fewer than $\frac{N}{10}$ or more than $\frac{9N}{10}$ entries is discarded.

Name	Age	Position	Salary
Alice	40	full time	120k
Carol			

Solution:

Q1=SELECT SUM(Salary) FROM Employees WHERE (Position='full time' OR Name=Carol) Q2=SELECT SUM(Salary) FROM Employees WHERE (Position='full time' AND Name≠Carol) Salary=Q1-Q2

If Carol is part time:

If Carol is full time:

		Q1	Q2	Q1-Q2
Full time				
	Carol			
Part time			·	

Q1-Q2 always gets Carol's salary!

2. SQL query attacks:

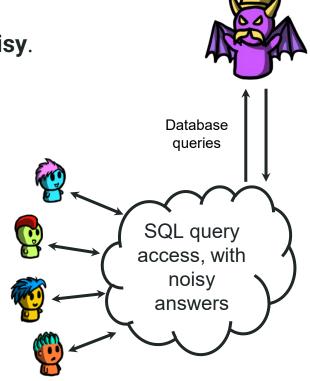

- The lesson is: even if the result of a query is harmless (too general), the combination of two or more queries can be very dangerous (very specific).
- Placing restrictions on individual queries, while still reporting exact values, does not work.
- When coming up with SQL query attacks in this setting:
 - Look for an attribute that you can use to make sure you always bypass the restriction so that the query goes through.
 - After you design the queries, check that they get the desired value regardless of the values of other attributes in the dataset (e.g., whether Carol was full or part time in the example).

3. Database Reconstruction Attacks: Dinur-Nissim

3. Database Reconstruction Attacks: Dinur-Nissim

- Now we are going to see an example where the adversary can issue queries but the answers are noisy.
- We consider the case where the adversary knows everything in the database except for one binary attribute, e.g.,

Name	Age	Position	Salary
Alice	40	?	120k
Bob	40	?	80k
Carol	32	?	150k

3. Database Reconstruction Attacks: Dinur-Nissim

 Since the adversary knows the primary key (Name), they can craft a condition that matches any specific number of rows, e.g.,

SELECT COUNT(*) FROM Employees WHERE (Name='Alice' OR Name='Carol') AND Position='full time'

Name	Age	Position	Salary
Alice	40	?	120k
Bob	40	?	80k
Carol	32	?	150k

True output:

- 0 if none are full time
- 1 if one is full time
- 2 if both are full time (But the system will only report noisy outputs)

Database

- Example: the DBMS adds noise uniformly chosen between -1, 0, 1.
- The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output
Alice	2
Bob	1
Bob, Alice	0
Carol	1
Carol, Alice	2
Carol, Bob	2
Carol, Bob, Alice	1

Example: the DBMS adds noise uniformly chosen between -1, 0, 1.

• The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output	
Alice	2	← Alice is full time
Bob	1	
Bob, Alice	0	
Carol	1	
Carol, Alice	2	
Carol, Bob	2	
Carol, Bob, Alice	1	

Example: the DBMS adds noise uniformly chosen between -1, 0, 1.

 The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output	
Alice	2	← Alice is full time
Bob	1	??
Bob, Alice	0	
Carol	1	
Carol, Alice	2	
Carol, Bob	2	
Carol, Bob, Alice	1	

- Example: the DBMS adds noise uniformly chosen between -1, 0, 1.
- The server queries for the sum of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output	
Alice	2	← Alice is full time
Bob	1	??
Bob, Alice	0	← Bob is part time
Carol	1	
Carol, Alice	2	
Carol, Bob	2	
Carol, Bob, Alice	1	

- Example: the DBMS adds noise uniformly chosen between -1, 0, 1.
- The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output	
Alice	2	← Alice is full time
Bob	1	??
Bob, Alice	0	← Bob is part time
Carol	1	← ??
Carol, Alice	2	
Carol, Bob	2	
Carol, Bob, Alice	1	

- Example: the DBMS adds noise uniformly chosen between -1, 0, 1.
- The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output	
Alice	2	← Alice is full time
Bob	1	??
Bob, Alice	0	└ Bob is part time
Carol	1	← ??
Carol, Alice	2	??
Carol, Bob	2	
Carol, Bob, Alice	1	

- Example: the DBMS adds noise uniformly chosen between -1, 0, 1.
- The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position
Alice	?
Bob	?
Carol	?

Rows	Output	
Alice	2	← Alice is full time
Bob	1	??
Bob, Alice	0	← Bob is part time
Carol	1	??
Carol, Alice	2	??
Carol, Bob	2	Carol is full time
Carol, Bob, Alice	1	

- Example: the DBMS adds noise uniformly chosen between -1, 0, 1.
- The adversary queries for the count of rows that have 'full time' AND a certain combination of names, and does this for every possible combination of names. These are the outputs:

Name	Position	
Alice	?	
Bob	?	
Carol	?	

Output		
2	← Alice is full time	Q: Can you tell who is
1	← ??	tir
0	← Bob is part time	
1	← ??	
2	← ??	
2	← Carol is full time	
1	Possible if both Car	rol and Alice are full time
	2 1 0 1 2	Alice is full time 1

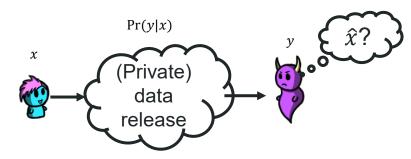

4. Statistical Inference

4. Statistical Inference: Probability recap

- The following attacks require some basic knowledge of probability and statistics. Let's do a recap.
- For simplicity, we assume *discrete* random variables here.
- x is Alice's private information, y is the leakage; usually \hat{x} is the adversary's estimate of x.
- Pr(x): the *prior* probability distribution of Alice's secret value
- Pr(y|x): the mechanism that models the leakage given Alice's secret information
 - o In Bayesian inference, Pr(y|x) is also called the *likelihood* (of x having generated y)
- Pr(x|y): the *posterior* probability distribution (the probability that x took a certain value given the observed leakage y)
- Bayes' theorem connects these concepts:

$$Pr(x|y) = \frac{Pr(y|x) \cdot Pr(x)}{Pr(y)}$$

• Law of total probability: $Pr(y) = \sum_{x} Pr(x) Pr(y|x)$

4. Statistical Inference: Probability recap

Recall the expected value of a random variable:

$$E\{x\} = \sum_{x} x \cdot \Pr(x)$$

 When the adversary sees y, they can compute the conditional expectation of x (leveraging the leakage y):

$$E\{x|Y=y\} = \sum_{x} x \cdot \Pr(x|y)$$

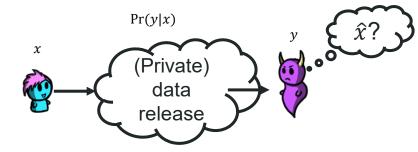

- Given y, Pr(x), and Pr(y|x), how do we run an attack (i.e., find x)?
 - o There are many options!

4. Statistical Inference: Maximum Likelihood

• The **Maximum Likelihood** (ML) approach simply looks for the *x* that is *most likely* to have generated *y*, i.e.,

$$\hat{x} = \operatorname*{argmax}_{x} \Pr(y|x)$$

Q: what is the downside of this?

4. Statistical Inference: Maximum Likelihood

 The Maximum Likelihood (ML) approach simply looks for the x that is most likely to have generated y, i.e.,

$$\hat{x} = \underset{x}{\operatorname{argmax}} \Pr(y|x)$$

Q: what is the downside of this?

A: Maybe that *x* had a very low prior probability...

- However, if the adversary does not know the prior, this is reasonable.
- · No need to compute the posterior!

4. Statistical Inference: Maximum A-Posteriori

• The **Maximum A-Posteriori** (MAP) approach chooses the *x* that maximizes the posterior probability:

$$\hat{x} = \operatorname*{argmax}_{x} \Pr(x|y)$$

• Expand the posterior and simplify the expression:

$$\hat{x} = \underset{x}{\operatorname{argmax}} \Pr(x|y) = \underset{x}{\operatorname{argmax}} \Pr(x) \cdot \Pr(y|x)$$

This is like ML, but taking into account the posterior. Note that we do not need to compute Pr(y)!

Q: when are MAP and ML equivalent?
 When the prior is uniform! (every secret value x is just as likely)

4. Statistical Inference: other attacks

- MAP and ML choose an x that maximizes a probability.
 Sometimes the attacker just wants to get an x that is "as close as possible" to the real x.
- Let $d(x, \hat{x})$ be a distance measuring how different x and \hat{x} are.

Q: What is the estimation of x (i.e., \hat{x}), that *minimizes* the *average distance* to x?

4. Statistical Inference: other attacks

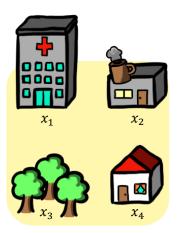

- MAP and ML choose an x that maximizes a probability.
 Sometimes the attacker just wants to get an x that is "as close as possible" to the real x.
- Let $d(x, \hat{x})$ be a distance measuring how different x and \hat{x} are.

Q: What is the estimation of x (i.e., \hat{x}), that *minimizes* the *average* (expected) distance to x?

$$\hat{x} = \underset{x'}{\operatorname{argmin}} E\{d(x, x')\} = \underset{x'}{\operatorname{argmin}} \sum_{x} \sum_{y} \Pr(x) \cdot \Pr(y|x) \cdot d(x, x')$$

Statistical Inference example: location privacy

- Alice wants to query for a location-based service, without revealing her real location x to the service provider. She runs a randomized mechanism Pr(y|x) and reports an obfuscated location y.
- Consider all locations are in a discrete set of only 4 possible locations: a hospital (x_1) , a café (x_2) , a forest (x_3) , and a house (x_4) .

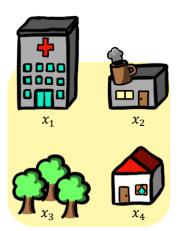

Pos.	Coordinates	Pr(x)
x_1	(0,1)	0.2
x_2	(1,1)	0.4
x_3	(0,0)	0.1
χ_4	(1,0)	0.3

Pr(y x)	$y = x_1$	$y = x_2$	$y = x_3$	$y = x_4$
$x = x_1$	0.5	0.2	0.2	0.1
$x = x_2$	0.2	0.5	0.1	0.2
$x = x_3$	0.2	0.1	0.5	0.2
$x = x_4$	0.1	0.2	0.2	0.5

The mechanism

Statistical Inference example: location privacy

- Alice wants to query for a location-based service, without revealing her real location x to the service provider. She runs a randomized mechanism Pr(y|x) and reports an obfuscated location y.
- Consider all locations are in a discrete set of only 4 possible locations: a hospital (x_1) , a café (x_2) , a forest (x_3) , and a house (x_4) .

Pos.	Coordinates	Pr(x)
x_1	(0,1)	0.2
x_2	(1,1)	0.4
x_3	(0,0)	0.1
x_4	(1,0)	0.3

Pr(y x)	$y = x_1$	$y = x_2$	$y = x_3$	$y = x_4$
$x = x_1$	0.5	0.2	0.2	0.1
$x = x_2$	0.2	0.5	0.1	0.2
$x = x_3$	0.2	0.1	0.5	0.2
$x = x_4$	0.1	0.2	0.2	0.5

The mechanism

Alice reports that she is in the forest $(y = x_3)$.

Q: What are the ML and MAP estimates of x?

Pos.	Coordinates	Pr(x)
x_1	(0,1)	0.2
x_2	(1,1)	0.4
x_3	(0,0)	0.1
x_4	(1,0)	0.3

Pr(y x)	$y = x_1$	$y = x_2$	$y = x_3$	$y = x_4$
$x = x_1$	0.5	0.2	0.2	0.1
$x = x_2$	0.2	0.5	0.1	0.2
$x = x_3$	0.2	0.1	0.5	0.2
$x = x_4$	0.1	0.2	0.2	0.5

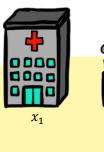

Pos.	Coordinates	Pr(x)
x_1	(0,1)	0.2
x_2	(1,1)	0.4
x_3	(0,0)	0.1
x_4	(1,0)	0.3

Pr(y x)	$y = x_1$	$y = x_2$	$y = x_3$	$y = x_4$
$x = x_1$	0.5	0.2	0.2	0.1
$x = x_2$	0.2	0.5	0.1	0.2
$x = x_3$	0.2	0.1	0.5	0.2
$x = x_4$	0.1	0.2	0.2	0.5

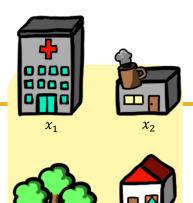

Pos.	Coordinates	Pr(x)
x_1	(0,1)	0.2
x_2	(1,1)	0.4
x_3	(0,0)	0.1
x_4	(1,0)	0.3

Pr(y x)	$y = x_1$	$y = x_2$	$y = x_3$	$y = x_4$
$x = x_1$	0.5	0.2	0.2	0.1
$x = x_2$	0.2	0.5	0.1	0.2
$x = x_3$	0.2	0.1	0.5	0.2
$x = x_4$	0.1	0.2	0.2	0.5

• ML:
$$\hat{x} = \underset{x}{\operatorname{argmax}} \Pr(y|x) = x_3$$

• MAP:
$$\hat{x} = \underset{x}{\operatorname{argmax}} \Pr(x) \cdot \Pr(y|x) = x_4$$

Pos.	Coordinates	Pr(x)
x_1	(0,1)	0.2
x_2	(1,1)	0.4
x_3	(0,0)	0.1
x_4	(1,0)	0.3

Pr(y x)	$y = x_1$	$y = x_2$	$y = x_3$	$y = x_4$
$x = x_1$	0.5	0.2	0.2	0.1
$x = x_2$	0.2	0.5	0.1	0.2
$x = x_3$	0.2	0.1	0.5	0.2
$x = x_4$	0.1	0.2	0.2	0.5

• MAP:
$$\hat{x} = \underset{x}{\operatorname{argmax}} \Pr(x) \cdot \Pr(y|x) = x_4$$

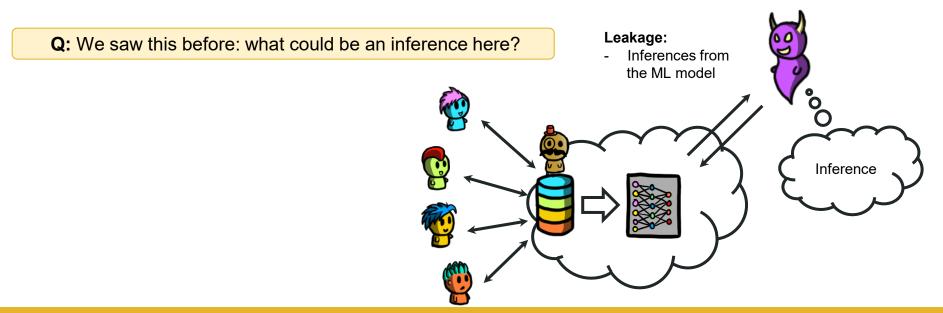

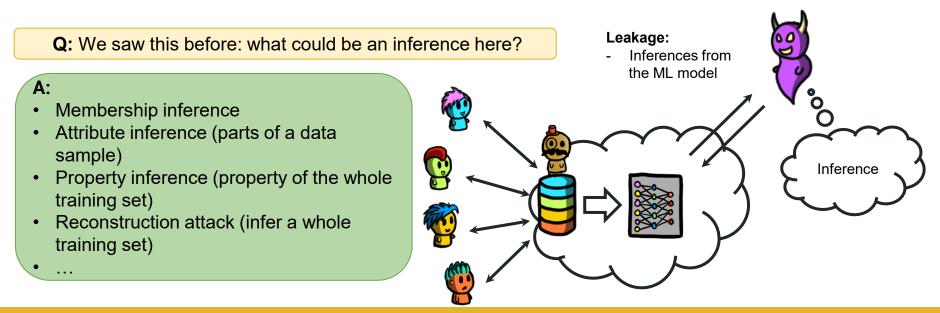

- There are many possible inference attacks in ML.
- For now, we will just think about the adversary goals and possible techniques

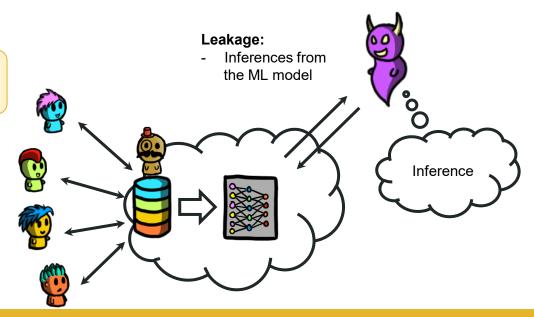

- There are many possible inference attacks in ML.
- For now, we will just think about the adversary goals and possible techniques

- There are many possible inference attacks in ML.
- For now, we will just think about the adversary goals and possible techniques

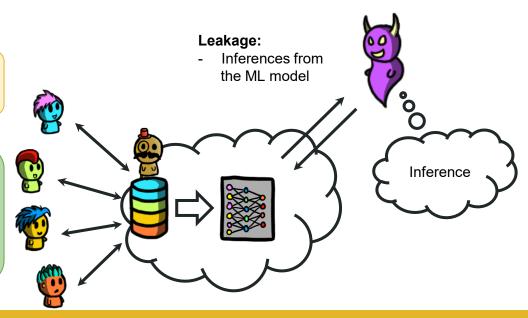

Q: If you were the adversary, which *techniques* would you use to run an attack in this scenario?

- There are many possible inference attacks in ML.
- For now, we will just think about the adversary goals and possible techniques

Q: If you were the adversary, which *techniques* would you use to run an attack in this scenario?

A: The idea is to use the fact that the model is more "confident" on samples it has trained on. We can use the confidence score, we can use thresholding techniques or train an ML model as an attack, etc.

6. Linking Attacks

6. Linking attacks

 As the name suggests, linking attacks find connections between two different sources of leakage that, alone, seem harmless.

Famous example, from [1]:

The Group Insurance Comission (GIC) in Massachusetts, sold data from 135,000 state employees to industry and researchers. They believed it was anonymous, so it was fine.

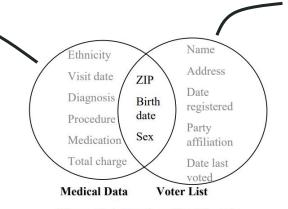

Figure 1 Linking to re-identify data

For \$20, you can purchase the voter registration list for Cambridge, Massachusetts

Fun fact: 87% (216 million of 248 million) of the population in the United States had reported characteristics that likely made them **unique** based only on {5-digit ZIP, gender, date of birth}

^[1] Sweeney, Latanya. "k-anonymity: A model for protecting privacy." International journal of uncertainty, fuzziness and knowledge-based systems 10.05 (2002): 557-570.

Conclusion

- Inference attacks are one way of quantifying the leakage of a mechanism empirically
 - Need to be cautious as:
 - What if a better attack is developed later
 - What if the assumptions of the attacks do not represent real world threats
- Next we'll look at defences
 - More theoretical way to measure privacy
 - Usually a lower bound on privacy leakage
